NEW JIMBLEBAR DRILL PROGRAM

Following encouraging exploration results, diversified Pilbara explorer, Warwick Resources has commenced a reverse circulation drilling program on its wholly owned Jimblebar gold project near Newman.

Warwick Resources Managing Director, Bruce McQuitty said recent aircore drilling, rock chip sampling and soil sampling programs had identified seven promising new gold targets that will be the subject of further investigation.

Warwick Resources field operations

“These results represent further exploration progress for Warwick Resources and vindicate the extensive exploration program we have in place across the historic Jimblebar region,” Mr McQuitty said.

Warwick is targeting predominantly open pit gold resources at Jimblebar, initially focusing on the Sunny South Prospect where shallow high-grade intersections have been identified.

The company said the current reverse circulation drilling program will also target the previously mined Shearer’s prospect for the first time.

A total of 111 aircore drill holes, 110 soil samples and 108 rock chip samples tested a 5km strike length of the Jimblebar mineralised trend on 100m to 400m spaced traverses in order to identify geochemical anomalies for subsequent drill targeting.

Warwick used aircore drilling to obtain samples of weathered bedrock in areas of transported cover, employing soil sampling in areas with limited amounts of outcrop and taking rock chip samples in areas where soil was absent, such as on the Jimblebar range of hills.
